

Integrating Global Server Load Balancing with the Existing DNS Infrastructure

<https://campus.barracuda.com/doc/19333841/>

In a typical GSLB deployment of the Barracuda Load Balancer ADC, the existing DNS domain nameserver continues as the authoritative nameserver for the zone or domain, for example, barracuda.com. But a hostname or sub-domain, for example, www, is delegated to the Barracuda Load Balancer ADC that acts as the GSLB Controller. When a DNS query for **www.barracuda.com** is received, it is forwarded to the GSLB Controller.

The GSLB Controller acts as the authoritative DNS server for delegated sub-domains, returning definitive answers to DNS queries about domain names installed in its configuration. On the GSLB Controller you can identify one or more IP addresses of sites that serve a single domain name. When asked to resolve a host, the GSLB Controller returns a list of IP addresses of the sites that are both available and that match the site selection algorithm.
