

Backing Up Microsoft SQL Server

<https://campus.barracuda.com/doc/43843616/>

You can watch a short video about backing up instances of a SQL Server databases.

You should have already configured Yosemite Server Backup SQL Agent. See [Configuring Backup for Microsoft SQL Server](#) for more information. Two additional concerns are present when you back up SQL Server database instances: setting the **Backup mode** of a job to **Full**, **Incremental** or **Differential**; and configuring Yosemite Server Backup to work with SQL Server's default backup routine.

Anytime Yosemite Server Backup returns an error message that is greater than 10000, a Microsoft SQL or Exchange error has occurred. Refer to your Microsoft documentation for more information as this is a Microsoft error code.

Microsoft SQL Server Databases and the Backup Mode

The **Backup mode** on the **Options** tab of a job that backs up SQL Server database instances is especially critical.

Backup modes

When the **Full** setting is selected, all files selected for backup are backed up, including SQL Server database instances and databases. However, when either the **Incremental** or **Differential** option is selected, Yosemite Server Backup backs up only the transaction logs for each database.

When the **Backup mode** is set to **Copy**, Yosemite Server Backup creates a full backup of the database but does not truncate the logs.

There is no difference between **Incremental** and **Differential** jobs for SQL Server databases.

Additional Conditions

Master, Model, MSDB and Pubs databases support only full backups. The **Backup mode** option is automatically set to **Full** when backing up these databases.

If you set a job to run in either **Incremental** or **Differential** mode and the job can only run as a full backup (as a result of the provision above), the job will fail to run on each of its initial passes, but will run in **Full** backup mode on its final pass.

Using Yosemite Server Backup with the SQL Server Backup Routine

Microsoft SQL Server has default utilities and commands for backing up data. When you use Yosemite Server Backup to back up SQL Server databases, you can still use these default SQL Server utilities and commands. For example, you can use the DUMP command to dump transaction logs to the dump device (preferably, a separate disk drive). You can set this up to occur at regular intervals, such as every 15 minutes or every hour. Next, you can create a backup job that backs up these transaction logs onto archival media every day.

In general, when you implement Yosemite Server Backup to back up your SQL Server databases, continue to use SQL Server's internal commands to duplicate and back up transaction logs. Set up a separate Yosemite Server Backup backup job to write these duplicated transaction logs to archival media.
