

How to Configure Time Server (NTP) Settings

<https://campus.barracuda.com/doc/43846833/>

Precise timekeeping is very important for the Barracuda NG Firewall and NG Control Center. HA synchronization, data accounting, NG Control Center configuration updates, logging, event notification, and other time-based services rely on a correct time system. The NTP daemon listens on port UDP/123 of the management IP address and, if remotely managed, the VIP address of the NG Firewall. The Barracuda NG Firewall supports two methods to synchronize the time:

- **NTP Servers** – The Barracuda NG Firewall acts as a client and retrieves and sets the time according to the time retrieved from the NTP server. You can use multiple NTP servers. The time deviation between the NTP server and the Barracuda NG Firewall must be less than 1000 seconds for the synchronization to succeed. To continuously synchronize the time with a NTP server, you must enable the NTP daemon on the NG Firewall. If multiple time servers are used, the time server with the lower stratum value is preferred.
- **NTP Peers** – To keep the time in your network synchronized when the NTP servers are unavailable, use the two-way NTP peer synchronization. NTP peers will converge toward a median time in multiple steps. No synchronization step can exceed two minutes. This means that two systems might take some time to synchronize. You can use MD5, SHA, SHA1, Ripe-MD160 and autokey authentication.

When you run the NTPd, your system becomes vulnerable to NTP exploits and UDP-based DoS attacks. Never use untrusted reference time servers or run a time server in a hostile environment.

In this article:

Step 1. Configure Time Settings

1. Go to **CONFIGURATION > Configuration Tree > Box > Administrative Settings**.
2. In the left menu, click **Time Settings / NTP**.
3. Click **Lock**.
4. Select your **Timezone** in the form *country/city*.

You can use Etc/GMT time, or UTC. Etc/GMT times do not support daylight saving time (DST). When using a Barracuda NG Control Center for multiple systems in different time zones, consider using UTC for all your systems.

5. Enable **Set HW Clock to UTC** to protect your system against unexpected time lapses caused by daylight saving time (DST).
6. Click **Send Changes** and **Activate**.

Step 2. Configure the Time Server

Configure the NTP servers you are using to set and synchronize the time for your Barracuda NG Firewall. NTP servers must be reachable from the management IP address of the NG Firewall or NG Control Center.

1. Go to **CONFIGURATION > Configuration Tree > Box > Administrative Settings**.
2. In the left menu, click **Time Settings / NTP**.
3. Click **Lock**.
4. Enable **NTP sync on Startup** to synchronize with an NTP server via ntpdate when starting. (You can also run an NTP daemon on the system for continuous time synchronization.)
5. In the **Time Server IP** table, add the IP address of the NTP time server(s). A remote, managed NG Firewall as an NTP server can be used by entering its VIP address.
6. Enable **Start NTPd** to synchronize the NTP daemon with the NTP time server(s).
7. Set the **Local Clock Stratum** value for the NTPd. If you are configuring an NG Control Center, make sure to use a stratum value lower than the default stratum (10) of the NG Firewall.
8. (optional) Select the events that you want to be notified about (Event-IDs 2070-2073) in **Event on NTPd**:
 - **start-failure (default)**
 - **+stop-failure**
 - **++start-success**
 - **+++stop-success**The list is additive. Events further down the list automatically include all the events that are listed before them.
9. Click **Send Changes** and **Activate**.

Step 3. (optional) Configure NTP Peers

Configure the NTP peers in your network. NTP peers should be on the same stratum. To authenticate NTP peers, you can choose between passphrase/MD5 and NTP autokey authentication. NTP peers must be reachable from the management IP address of the NG Firewall.

1. Go to **CONFIGURATION > Configuration Tree > Box > Administrative Settings**.
2. In the left menu, click **Time Settings / NTP**.
3. Click **Lock**.
4. In the **Time Peers** section, click **+** to add your NTP peers. The **Time Peers** window opens.
5. Specify the following settings for each peer:
 - **Peer IP Address** – Enter the IP address for the NTP peer.
 - **Peer Authentication Type** – Select **None**, **MD5**, **SHA**, **SHA1**, **Ripe-MD160** or **Autokey** authentication.
 - **(MD5,SHA,SHA1, RipeMD160 authentication only) Peer Authentication ID** – Enter

- a number between 0 and 1000000. You must use the same Peer Authentication ID on all peers.
- **(MD5,SHA,SHA1, RipeMD160 authentication only) Peer Authentication** - Enter the NTP peer authentication string.
 - **(Autokey authentication only) Peer Host Name** - Enter the FQDN for the trusted NTP peer.
 - **(Autokey authentication only) Trusted Public Key** - Import the public key for the NTP peer.
6. Click **OK**.
 7. If you are using NTP autokey authentication, click **Set** next to **NTP Autokey Configuration**. The **NTP Autokey Configuration** window opens.
 1. Enter the **NTP Key Password** which is used to encrypt the private key.
 2. Click **Create New NTP Key**.
 3. Click **OK**. The NTP certificate is created.
 4. Click **Ex/Import** and select **Export to File**. Use the public key to authenticate to other NTP peers.
 8. Click **Send Changes** and **Activate**.

Event Processing

The event setting only pertains to NTPd behavior during controlled start or stop sequences. You will not be notified when NTPd is killed manually or just dies unexpectedly. Events are also triggered when the NTPd is restarted on the [Box Page](#) with the following options:

- **Restart NTP** - The control daemon restarts the NTPd.
- **Sync** - Starts the synchronization processes with the *ctrltime* script, which stops the NTPd and then executes *ntpdate* on port 123.

NTP Troubleshooting

On the command line, enter: `ntpq -p` to check which NTP servers and peers your Barracuda NG Firewall is using. See below for an example of an NG Firewall using one NTP server (10.0.10.44) and three NTP peers. For more information, see <http://ntp.org>

```
[root@HQ-NG2:~]# ntpq -p
      remote                refid              st t when poll reach  delay  offset  jitter
=====
LOCAL(0)                .LOCL.             10 l 1810   16    0   0.000   0.000   0.000
*10.0.10.44              194.11.27.31      3 u  22    32   377   0.396  -0.807   0.102
