

## Forward Error Correction (FEC) in TINA Tunnels

<https://campus.barracuda.com/doc/96026171/>

Forward error correction (FEC) is a special technique for detecting and correcting errors during data transmission between two peers. The term "Forward" indicates that erroneous or lost packets can be reconstructed at the receiver's side without the need of retransmitting the missing information by the sender.

Unlike TCP, which has its own error detection and correction mechanism, UDP is a connectionless protocol that does not include additional information for error detection and correction. This is where FEC comes into play by adding redundant information for repairing damaged or even lost packets during UDP transmissions with the benefit of being much faster than TCP with its protocol-based feature of retransmission.

Forward error correction requires CPUs that support SSE3 instructions.

### Situations and Scenarios when (not) to Use FEC

- FEC is best suited for use cases that rely on UDP-based interactive traffic, e.g., VoIP.
- FEC is not useful for TCP-based traffic because TCP uses its own generic error correction mechanism, and, therefore, the combination of TCP and FEC may be too slow to avoid glitches.
- FEC is not well suited for higher-level bulk data transfers (e.g., HTTP/FTP) that use TCP as the base protocol, for example, backup systems, large file transfers, etc.

For this reason, FEC is available only for TINA/UDP tunnels on the CloudGen Firewall.

### Considerations when Using FEC

Because FEC uses additional packets for repairing damaged or lost traffic, additional bandwidth is required. Certain aspects must be considered when using FEC:

- The FEC level is configurable per transport and direction (asymmetric FEC is also possible).
- The FEC level configured on a box determines the amount of outgoing FEC, that is, the number of repair packets being sent.
- The actual amount of FEC packets depends on the current link loss. As a consequence, FEC is only available if **Dynamic Bandwidth Detection** is enabled.
- FEC cannot repair sustained periods of loss.
- If data loss is caused by congestion, FEC will make matters even worse.
- In case FEC has recovered UDP-based interactive traffic, the affected packets will effectively arrive with some delay, which is still less than the time for TCP retransmissions.

### FEC-Level Properties for CGFs

When FEC is activated, the amount of error detection and correction can be configured for one of three levels. Each level stands for a certain number of repair packets sent:

	Level	CGF	CGW
0.	Off		
1.	Low	Y	-
2.	Medium	Y	Y
3.	High	Y	-

On a CGW, the FEC level cannot be adjusted and is set to **Medium**.

Each of these three levels is associated with certain marginal values that determine the specific behavior of the respective FEC level:

- **Maximum Link Loss** - This is the maximum amount of packet loss on the link, so that the average packet loss after FEC remains under 0.1%.
- **Maximum Overhead** - This is the maximum amount of FEC repair packets that are added to the stream of UDP packets. Depending on the measured link loss level, the actual overhead is usually much lower.
- **Maximum Burst** - This is the maximum amount of consecutively lost packets that can be repaired.

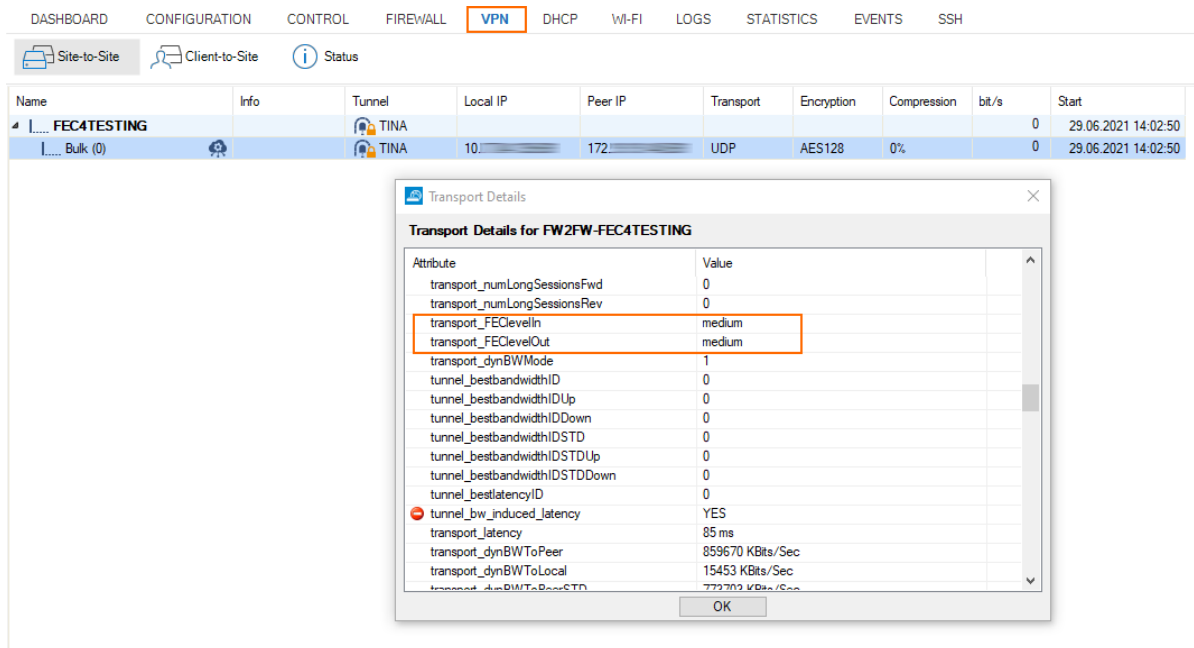

The following table displays these three parameters depending on the three possible FEC levels:

Level	Max. Link Loss	Max. Overhead	Max. Burst
-------	----------------	---------------	------------

Low	2%	12.5%	17
Medium	5%	25%	21
High	15%	50%	41

## Feedback and Monitoring

The limiting loss level of the sender's side can be inspected in the **VPN tab -> Site-to-Site -> right click your TINA transport -> Show Transport Details...**, window **Transport Details**.

The screenshot shows the Barracuda CloudGen Firewall interface. The top navigation bar includes DASHBOARD, CONFIGURATION, CONTROL, FIREWALL, **VPN**, DHCP, WI-FI, LOGS, STATISTICS, EVENTS, and SSH. Under the VPN tab, there are three sub-tabs: Site-to-Site, Client-to-Site, and Status. The Site-to-Site sub-tab is active, showing a table of VPN tunnels. The first tunnel is named 'FEC4TESTING' and is of type 'TINA'. The table columns are Name, Info, Tunnel, Local IP, Peer IP, Transport, Encryption, Compression, bit/s, and Start. The 'FEC4TESTING' tunnel has a Local IP of 10.10.10.1 and a Peer IP of 172.17.0.1. The Transport is UDP, Encryption is AES128, and Compression is 0%. The bit/s is 0 and the Start time is 29.06.2021 14:02:50.

The 'Transport Details' window is open, showing details for the 'FEC4TESTING' tunnel. The window title is 'Transport Details for FW2FW-FEC4TESTING'. It contains a table with two columns: Attribute and Value. The attributes and their values are:

Attribute	Value
transport_numLongSessionsFwd	0
transport_numLongSessionsRev	0
transport_FEClevelIn	medium
transport_FEClevelOut	medium
transport_dynBWMode	1
tunnel_bestbandwidthID	0
tunnel_bestbandwidthIDUp	0
tunnel_bestbandwidthIDDown	0
tunnel_bestbandwidthIDSTD	0
tunnel_bestbandwidthIDSTDUp	0
tunnel_bestbandwidthIDSTDDown	0
tunnel_bestlatencyID	0
tunnel_bw_induced_latency	YES
transport_latency	85 ms
transport_dynBWToPeer	859670 KBits/Sec
transport_dynBWToLocal	15453 KBits/Sec
transport_dynBWToPeerSTD	773702 KBits/Sec

The 'transport\_FEClevelIn' and 'transport\_FEClevelOut' attributes are highlighted with an orange box, indicating the limiting loss level of the sender's side.

For more information on using FEC, see [How to Activate Forward Error Correction](#).
